ABS Design and Active Suspension Control Based on HOSM

Juan Diego Sánchez-Torres, Alejandra Ferreira de Loza, Marcos I. Galicia and Alexander G. Loukianov

Abstract—This paper tackles the control of a brake assisted with an active suspension. The goal of the paper is ensure an effective braking process improving the vehicle safety in adverse driving conditions. To address this, the wheel slip ratio is kept to a desired value reducing the effective braking distance by designing of a robust tracking controller based on high order sliding modes algorithms, imposing the anti-lock brake system feature. On the other hand, the active suspension problem is carried with a nested backward sliding surface design. The purpose of this control is to improve the driving comfort. To this aim, the designed controller compensate the effects of the unmatched perturbation coming from the road. This controller exploits a high order sliding modes observer, which guarantees theoretically exact state and perturbation estimation. In both cases, a continuous control action drives the state trajectories to the designed sliding manifolds and keeps them there in spite of the matched and unmatched perturbations. The feasibility of the proposed scheme has been exposed via simulations.

I. INTRODUCTION

The aim of this paper is to propose robust controllers based on sliding mode (SM) algorithms for a brake coupled with an active suspension. The main difficulties of controller design in automotive systems are related to high non-linearities, uncertainties caused by external perturbations and parameter variations which are unknown. In order to deal with these problems, several researchers have proposed robust control approaches, including those based on SM algorithms [1], [2], [3] and, [4]; considering the problem of ABS design with extremum seeking controllers in order to maximize the tire/road friction [5] and, the analysis of the nonlinear dynamics on these systems [6]. Similarly, there are solutions for the active suspension case [7]. For the case of the ABS and active suspension as a whole system, a backstepping design is presented in [8]; however, for this case the road disturbances are assumed to be known in order to facilitate the control law design. Also for the whole system, in [9] a SM controller with a sliding manifold designed using geometric decoupling methods to disturbance rejection, was proposed.

The SM algorithms, are proposed with the idea to drive the dynamics of a system to a sliding manifold, that is an integral manifold with finite reaching time [10]; exhibiting features such as finite time convergence, robustness to uncertainties and insensitivity to external bounded disturbances [11].

In this work, a controller design for an ABS assisted with an active suspension. Taking advantage of the SM algorithms features, the brake controller is proposed such that it imposes the anti-lock brake system ABS property in finite time in spite of perturbations. The ABS forces a desired vehicle motion and, as a consequence, its stability. Similarly, the active suspension is controlled with the objective of guaranteeing the ride quality and comfort for the passengers by reducing the vibration due to the road shape.

These controllers are based on the application of high order sliding modes (HOSM) algorithms [12]. The use of these methods allows the design of robust controllers in presence of external disturbances and parametric variations, which are supposed to be unknown but with a known bound. The main feature of the proposed controllers is the characteristic of exact finite time rejection of both, the matched and the unmatched perturbations, improving the safety and the comfort of the vehicle.

To assess the performance of the designed controllers, the closed loop system is tested by means of numerical simulation.

In the following, Section II presents the considered model. Sections III and IV describe the proposed controllers for the ABS and active suspension problems, including a detailed analysis of stability and robustness. The successful simulations are presented in section V. Finally, in Section VI the conclusions are given.

II. MATHEMATICAL MODEL

In this section, we consider a quarter of vehicle model, this model includes the active suspension, the pneumatic brake system, the wheel motion and the longitudinal vehicle motion.

A. Active Suspension Model

The quarter-car active suspension is a 2-DOF mechanical system shown in Fig. 1.

This system connects the car body and the wheel masses and is modeled as a linear viscous damper and a spring
elements, whereas the tire is represented as a linear spring and damping elements. The motion equations for this system are given by

\[
\begin{align*}
\dot{z}_c &= -K_{cw}(z_c - z_{w}) - C_{cw}(\dot{z}_c - \dot{z}_{w}) + f_{ha} \\
\dot{z}_w &= K_{cw}(z_c - z_{w}) + C_{cw}(\dot{z}_c - \dot{z}_{w}) - K_{wr}(z_w - z_r) - C_{wr}(\dot{z}_w - \dot{z}_r) - f_{ha}
\end{align*}
\]

where \(m_c\) and \(m_w\) are the mass of the car and the wheel, respectively, \(z_c\) is the car vertical displacement, \(z_w\) is the wheel vertical displacement, \(K_{cw}\) and \(K_{wr}\) are the spring coefficients, \(C_{cw}\) and \(C_{wr}\) are the damping coefficients, \(f_{ha}\) is the force of the hydraulic actuator, \(z_r\) is the disturbance due to road and \(\dot{z}_r\) is its time derivative.

**B. Pneumatic Brake System Equations**

The specific configuration of this system considers the brake disk, which holds the wheel, as a result of the increment of the air pressure in the brake cylinder. The entrance of the air through the pipes from the central reservoir and the expulsion from the brake cylinder to the atmosphere is regulated by a common valve. The time response of the valve is considered small, compared with the time constant of the pneumatic system.

![Fig. 2. Pneumatic brake scheme.](image)

Considering Fig. 2, we suppose the brake torque \(T_b\) is proportional to the pressure \(P_b\) in the brake cylinder

\[ T_b = k_b P_b \]  

with \(k_b > 0\). For the brake system we use an approximated model of pressure changes in the brake cylinder due to the opening of the valve with a first order relation [13], this relation can be represented as

\[ \tau \dot{P}_b + P_b = P_c \]  

where \(\tau\) is the time constant of the pipelines, \(P_c\) is the pressure inside the central reservoir. The atmospheric pressure, \(P_a\), is considered equal to zero.

**C. Wheel Motion Equations**

To describe the wheels motion, a partial mathematical model of the dynamic system is used [14]. The dynamics of the angular momentum variation relative to the rotation axis, are given by

\[ J\ddot{\omega} = -rf(s) - b_\omega \omega - T_b \]  

where \(\omega\) is the wheel angular velocity, \(J\) is the wheel inertia moment, \(r\) is the wheel radius, \(b_\omega\) is a viscous friction coefficient due to wheel bearings and \(f(s)\) is the contact force of the wheel.

The expression for longitudinal component of the contact force in the motion plane is

\[ f(s) = \mu f_m \phi(s) \]  

where \(\mu\) is the nominal friction coefficient between the wheel and the road, \(f_m\) is the normal reaction force in the wheel

\[ f_m = mg + \Delta f_m(z_r, \dot{z}_r) \]  

with \(m\) equal to the mass supported by the wheel, \(g\) is the gravity acceleration and \(\Delta f_m(z_r, \dot{z}_r) = -K_{wr}(z_w - z_r) - C_{wr}(\dot{z}_w - \dot{z}_r)\) represents the variation of normal reaction force due to road perturbation. The function \(\phi(s)\) represents a friction/slip characteristic relation between the tire and road surface. Here, we use the Pacejka model [15], [16], defined as follows

\[ \phi(s) = D \sin \left( C \arctan \left( B s - E \left( B s - \arctan \left( B s \right) \right) \right) \right) \]  

The slip rate \(s\) is defined as

\[ s = \frac{v - r_\omega}{v} \]  

where \(v\) is the longitudinal velocity of the wheel mass center. The equations (2)-(7) characterize the wheel motion.

**D. The Vehicle Motion Equation**

The vehicle longitudinal dynamics without lateral motion is considered. The main reasons for this assumptions are that the steering angle changing has virtually no effect on the force vectors on the wheels. Then, the vehicle longitudinal dynamics is written as

\[ M\ddot{v} = -F(s) - F_a(v) \]  

where \(M\) is the vehicle mass, \(F_a(v)\) is the aerodynamic drag force, which is proportional to the vehicle velocity and is defined as

\[ F_a(v) = \frac{1}{2} \rho C_d A_f \left( v + v_w \right)^2 + \Delta v_w \]  

where \(\rho\) is the air density, \(C_d\) is the aerodynamic coefficient, \(A_f\) is the frontal area of vehicle, \(v_w\) is the wind velocity and \(\Delta v_w\) represents its variations.

As in the expression for longitudinal component of the contact force in the motion plane (5), the contact force of the vehicle \(F(s)\) is modeled of the form

\[ F(s) = \mu \phi(s) f_M \]  

where \(\mu\) is the nominal friction coefficient between the wheel and the road, \(f_M\) is the normal reaction force of the vehicle

\[ f_M = Mg + \Delta f_M(z_r, \dot{z}_r) \]  

with \(M\) equal to the vehicle mass, \(g\) is the gravity acceleration and \(\Delta f_M(z_r, \dot{z}_r) = -K_{wr}(z_w - z_r) - C_{wr}(\dot{z}_w - \dot{z}_r)\) represents the variation of normal reaction force due to road perturbation.
E. State Space Equations

The dynamic equations of the whole system (3)-(8) rewritten using the state variables
\[ \mathbf{x} = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & x_7 \end{bmatrix}^T \]
results in the following form:
\[ \begin{cases} 
    \dot{x}_1 = x_2 \\
    \dot{x}_2 = -a_1 (x_1 - x_3) - a_2 (x_2 - x_4) + b_1 u_s \\
    \dot{x}_3 = x_4 \\
    \dot{x}_4 = a_3 (x_1 - x_3) + a_4 (x_2 - x_4) - a_5 x_3 - a_6 x_2 + b_2 u_s + \Delta_r \\
    \dot{x}_5 = -a_7 x_5 - a_8 f(w) - a_9 x_6 + \Delta_\lambda \\
    \dot{x}_6 = -a_{10} x_6 + b_3 u_b + \Delta_2 \\
    \dot{x}_7 = -a_{11} F(s) - f_w(x_7) + \Delta_3 
\end{cases} \quad (11) \]

with the outputs
\[ y_s = [ x_1 \quad x_3 ] \quad \text{and} \quad y_b = [ x_5 \quad x_7 ] \]

where \( a_1 = K_c w/m_c, a_2 = C_{cw}/m_c, a_3 = K_c w/m_c, \)
\( a_4 = C_{cw}/m_w, a_5 = K_{cw}/m_w, a_6 = C_{cw}/m_w, a_7 = b_1/J, \)
\( a_8 = r/J, a_9 = b_3/J, a_{10} = 1/\tau, a_{11} = 1/M, b_1 = 1/m_c, \)
\( b_2 = 1/m_w, b_3 = 1/\tau, u_s = f_{ha}, u_b = P_c \) and \( f_w(x_7) = \frac{1}{m_w} (pC_d A_f)(x_7 + v_w)^2. \)

Here, \( \Delta_\lambda = a_9 z_r + a_6 z_r, \) the term \( \Delta_r \) contains the variations of the friction parameters \( \mu, b_3, \) wheel inertia moment \( J \) and the normal reaction force due to road perturbation \( \Delta f_m(z_r, z_r). \) The term \( \Delta_2 \) contains the variations of the parameters \( \tau \) and \( P_c. \) Finally, the term \( \Delta_3 \) contains the variations of the parameters \( \mu, C_d, A_f, \rho, \) wind velocity variation \( \Delta v_w \) and the force due to road perturbation \( \Delta f_M(z_r, z_r). \)

III. ACTIVE SUSPENSION CONTROLLER DESIGN

In this section, a HOSM observer to estimate the state and identify the unknown inputs in finite time is used. Then, a sliding manifold is designed such that the system’s motion along the manifold meets the regulation of the system state and the rejection of perturbations coming from the road.

Define \( x_s = [ x_1 \quad x_2 \quad x_3 \quad x_4 ]^T, \) then the subsystem (11) is represented of the form
\[ \begin{align*}
    \dot{x}_s &= A_s x_s + B_s u_s + D_s \Delta_r \\
    y_s &= C_s x_s
\end{align*} \quad (13) \]

where
\[ A_s = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -a_1 & -a_2 & a_3 & a_4 \\ 0 & 0 & -a_3 & a_5 \\ a_1 & a_4 & a_5 & -a_4 \end{bmatrix}, \\
B_s = \begin{bmatrix} 0 & b_1 & 0 & -b_2 \end{bmatrix}^T, \\
C_s = \begin{bmatrix} 1 & 0 & 1 & 0 \end{bmatrix} \quad \text{and},
\]
\[ D_s = \begin{bmatrix} 0 & 0 & 0 & 1 \end{bmatrix}^T. \]

Assuming that there is a constant \( \Delta_\lambda^+ \) such that the perturbation as well as its successive derivatives are bounded, i.e. \( |\Delta_\lambda| \leq \Delta_\lambda^+, \Delta_\lambda^+ \leq \Delta_\lambda^+ \) for all \( t \geq 0. \) An algebraic HOSM observer is proposed in order to estimate the state and identify the perturbation. Next subsection is devoted to summarize the observer design, for further details see [17].

A. State Observation and Unknown Input Identification

For estimation purposes system (13) is strongly observable or equivalently for \( u_s = 0 \) the triplet \( (A_s, D_s, C_s) \) has no zeros. Consequently, the state estimation can be achieved from the output and its derivatives. Beforehand the estimation error must be bounded. Consider the following auxiliary system:
\[ \dot{\hat{x}}_s = A_s \hat{x}_s + B_s u_s + L (y_s - \hat{y}_s) \quad (14) \]
where \( \hat{y}_s = C_s \hat{x}_s \) and \( \hat{x}_s \) is the estimate of \( x_s, \) matrix \( L \) must be designed such that the matrix \( \hat{A} := (A_s - LC_s) \) is Hurwitz. Defining the error \( x_e := x_s - \hat{x}_s, \) from (13)-(14) it follows:
\[ \dot{x}_e = \hat{A} x_e + D_s \Delta_r. \quad (15) \]

Thus, the error \( x_e(t) \) is ultimately bounded, i.e., there exist a known constant \( \delta_\epsilon > 0 \) and a finite time \( t_e, \) such that \( ||x_e(t)|| \leq \delta_\epsilon, \) for all \( t > t_e. \)

Defining the output of the linear error system \( y_e := y_s - \hat{y}_s, \) let us construct an extended vector considering the output vector and the derivative of a linear combination of the output unaffected by the perturbations, i.e.
\[ \frac{d}{dt} \begin{bmatrix} C_s D_s y_e \end{bmatrix} = \begin{bmatrix} (C_s D_s)^+ C_s \hat{A} & \frac{C_s D_s}{I_2} \end{bmatrix} x_e. \quad (16) \]

Due to the strongly observability property of the system (13), it can be shown that matrix \( M_s \) has full rank (see, e.g., [18]). This means that the algebraic equation (16) has a unique solution for \( x_e. \) Hence, rearranging the previous equation and pre-multiplying both sides by \( M_s^+ := (M_s^T M_s)^{-1} M_s^T \) it yields to
\[ x_e = \frac{d}{dt} M_s^+ \begin{bmatrix} (C_s D_s)^+ C_s \hat{A} & 0 \end{bmatrix} \begin{bmatrix} y_e \end{bmatrix} \quad (17) \]

Following [19], under the boundedness assumption of \( \Delta_r \leq \Delta_\lambda^+ \) a third order sliding mode differentiator can be constructed
\[ \begin{align*}
    \nu_0 &= -5 \Lambda^+ \Psi^2 (\nu_0 - Y_s) + \nu_1 \\
    \nu_1 &= -3 \Lambda^+ \Psi^2 (\nu_1 - \nu_0) + \nu_2 \\
    \nu_2 &= -1.5 \Lambda^+ \Psi^2 (\nu_2 - \nu_1) + \nu_3 \\
    \nu_3 &= -1.1 \Lambda \Psi^2 (\nu_3 - \nu_2)
\end{align*} \quad (18) \]

where \( \nu_i \in \mathbb{R}^2 \) for \( i = 0, \ldots, 3 \) are the outputs of the differentiator, the function vector is defined as \( \Psi^k (\nu_i) \)
\( \begin{bmatrix} |v_{i1}|^k \text{sign}(v_{i1}) & |v_{i2}|^k \text{sign}(v_{i2}) \end{bmatrix}^T \) with \( k \in \mathbb{R} \) and \( \Lambda \) is a Lipschitz constant of function \( Y_s \) and can be figured from (15) as \( \Lambda \geq ||\hat{A}||^2 e^r + ||\hat{A} D_s + D_s|| \Delta_\lambda^+. \)

In [19] it was shown that there is a finite time \( t_f \) such that the identity \( \nu_i = \frac{d}{dt} Y_s \) is achieved for every \( i = 0, \ldots, 3. \)
The vector $x_e$ can be reconstructed from the first sliding dynamics, i.e. $\nu_1 = x_e$ accordingly

$$\dot{x} := \nu_1 + \dot{x}$$

where $\dot{x}$ represents the estimated value of $x$. Therefore, the identity $\dot{x} \equiv x$, for all $t \geq t_f$ holds.

Thus, for identifying the unknown inputs, from (18) we can recover $\dot{x}_e$, i.e. $\nu_2 = \dot{x}_e$ for all $t \geq t_f$ and from (15) it follows that

$$\dot{\Delta}_r := -D^+_s \left[ \hat{A} \nu_1 - \nu_3 \right]$$

and consequently the derivative of (15) yields to

$$\dot{\Delta}_r := -D^+_s \left[ \hat{A} \nu_2 - \nu_3 \right]$$

where $\Delta_r$ and $\hat{\Delta}_r$ represent the estimated values of $\Delta_r$ and $\hat{\Delta}_r$. Therefore, the identities $\hat{\Delta}_r \equiv \Delta_r$ and $\hat{\Delta}_r \equiv \Delta_r$ are fulfilled for all $t \geq t_f$.

**B. Nested Backward Sliding Control**

Applying twice the regular form [20], the system (13) is transformed into $\vec{x}_{11} = x_1 + \frac{b_1}{b_2} x_3$, $\vec{x}_{12} = x_2 + a_r x_3 + \frac{b_1}{b_2} x_4$, $\vec{x}_2 = x_3$ and $\vec{x}_3 = x_4$.

Where $a_r = -a_2 + \frac{b_2}{b_1} (a_4 + a_6 - a_2) + a_4 \left( \frac{b_2}{b_1} \right)^2$ and the transformed system yields to

$$\dot{\vec{x}}_1 = A_1 \vec{x}_1 + B_1 \vec{x}_2 + D_1 \Delta_r$$
$$\dot{\vec{x}}_2 = A_21 \vec{x}_1 + A_22 \vec{x}_2 + \vec{x}_3 + D_2 \Delta_r$$
$$\dot{\vec{x}}_3 = A_31 \vec{x}_1 + A_32 \vec{x}_2 + A_33 \vec{x}_3 + u_s + D_3 \Delta_r$$

where $\vec{x}_1 \in \mathbb{R}^2$, $\vec{x}_2$, $\vec{x}_3 \in \mathbb{R}$, and the matrices are of the corresponding dimensions. Since the system (19) satisfies the matching condition $\text{span} \{ D_1 \} \subset \text{span} \{ B_1 \}$, there exist a matrix $\Gamma$ such that $B_1 \Gamma = D_1$ [21]. To this end $\vec{x}_2$ can be exploited and regarded as an input $\vec{x}_2 = -K \vec{x}_1 - \Gamma \Delta_r$ then $\vec{x}_1 = (A_1 - B_1 K) \vec{x}_1$.

In the ideal case $\hat{\Delta}_r \equiv \Delta_r$ and $D_1 (\Delta_r - \hat{\Delta}_r) = 0$. The gain $K$ is designed such that $A_1 := A_1 - B_1 K$ is Hurwitz. With this aim, let us design the auxiliary variable $\xi = \vec{x}_2 + K \vec{x}_1 + \Gamma \hat{\Delta}_r$ and from (19)-(20) it yields to

$$\dot{\xi} = \hat{A}_1 \vec{x}_1 + B_1 \xi$$
$$\dot{\xi} = \hat{A}_21 \vec{x}_1 + \hat{A}_22 \xi + \hat{D}_2 \Delta_r + \Gamma \hat{\Delta}_r + \vec{x}_3$$

where $\hat{A}_21 = A_21 - A_22 K - K \hat{A}_1$, $\hat{A}_22 = A_22 + K B_1$, $\hat{D}_2 = D_2 - A_22 \Gamma$.

Now, $\vec{x}_3$ will be designed to stabilize (22). Consider a Lyapunov candidate function $V(\vec{x}_1, \xi) = \vec{x}_1^T P \vec{x}_1 + \xi^T \xi$, where $P$ is a symmetric positive definite matrix satisfying $PA + A^T P = -I$. Thus, designing

$$\vec{x}_3 = - \left( (\hat{A}_21 + B_1^T P) \vec{x}_1 + (\hat{A}_22 + I) \xi + \hat{D}_2 \Delta_r + \Gamma \hat{\Delta}_r \right)$$

yields to $\dot{V} \leq - \| \vec{x}_1 \|^2 - \| \xi \|^2$. In the ideal case, the coordinates $\vec{x}_1$, $\xi$ will be exponentially stable. Finally, the coordinate $\vec{x}_1$ is exponentially stable, i.e. there exist constants $\alpha_1$, $\alpha_2 > 0$, such that $\| \vec{x}_1 \| \leq \alpha_1 \| \vec{x}_1(0) \| \exp^{-\alpha_2 t}$ for all $t > t_r$, with $t_r > 0$, and the remaining trajectories will be bounded, i.e. $\| \vec{x}_2 \| \leq |K \vec{x}_1| + |\Gamma| \Delta_r$ and from (23) there exist some $\Phi > 0$, such that $| \vec{x}_3 | \leq \Phi | \vec{x} | + | \Gamma + D_2 | \Delta_r ^+$ for all $t > t_r$.

Considering (23), the sliding manifold takes the form

$$\sigma = \vec{x}_3 + \varphi (\vec{x}_1, \vec{x}_2, \hat{\Delta}_r, \hat{\Delta}_r)$$

where $\varphi (\vec{x}_1, \vec{x}_2, \hat{\Delta}_r, \hat{\Delta}_r) = (A_21 + B_1^T P + (\hat{A}_22 + I) \Delta_r) \vec{x}_1 + (\hat{A}_22 + I) \vec{x}_2 + (\hat{D}_2 + (\hat{A}_22 + I) \Gamma) \Delta_r + \Gamma \hat{\Delta}_r$.

The dynamics of the sliding variable (24) is given by

$$\dot{\sigma} = A_31 \vec{x}_1 + A_32 \vec{x}_2 + A_33 \vec{x}_3 + D_3 \Delta_r + u_s + \varphi (\vec{x}_1, \vec{x}_2, \hat{\Delta}_r, \hat{\Delta}_r)$$

To induce SM on the manifold $\sigma = 0$, the super-twisting control algorithm [12] is applied to (25)

$$u_s = u_{s_1} + u_{s_2}$$

with $u_{s_1} = - (A_31 \vec{x}_1 + A_32 \vec{x}_2 + A_33 \vec{x}_3 + D_3 \Delta_r) - k_{s_1} |\sigma|^{\frac{1}{2}} \text{sign}(\sigma)$, $u_{s_2} = -k_{s_2} \text{sign}(\sigma)$ and $k_{s_1}, k_{s_2} > 0$.

The stability condition for the system (25) closed-loop by (26), can be obtained via the transformation $q_s = u_s + \varphi (\vec{x}_1, \vec{x}_2, \hat{\Delta}_r, \hat{\Delta}_r)$ to

$$\dot{q}_s = -k_{s_1} |\sigma|^{\frac{1}{2}} \text{sign}(\sigma) - q_s$$

Under the assumption $|\varphi (\vec{x}_1, \vec{x}_2, \hat{\Delta}_r, \hat{\Delta}_r)| < \delta_\sigma < \infty$ and choosing $k_{s_1} > 0$ and $k_{s_2} > 3 \delta_\sigma + 4 \left( \frac{\Sigma}{x_{s_1}} \right)^2$ then $(\sigma, q_s) = (0, 0)$ in finite time [23]. Establishing a SM in the manifold $\sigma = 0$.

**IV. BRAKE CONTROLLER**

Consider the brake subsystem (12), defining $x_b = [\begin{array}{c} x_5 \ x_6 \ x_7 \end{array}]^T$, taking into account the slip equation (7), the direct action of the pressure $P_t$ in the brake cylinder over the wheels motion, and the measurements of $y_b = [\begin{array}{c} x_5 \ x_7 \end{array}]$, the tracking error $e_1$ is defined as

$$e_1 \triangleq x_5 - 1 - s^* x_7.$$

Note that if $e_1 = 0$, then $s = s^*$. This results in the maximum friction force, minimizing the braking time until the wheel locking is avoided.

Straightforward calculations reveal that it is possible to write $x_3$ and $x_7$ in terms of $e_1$. From (11), (12) and (28) the dynamics of $e_1$ can be written in the Nonlinear Block Controllable with perturbation form [24]

$$\dot{e}_1 = f_1 (e_1) + b_1 (e_1) x_6 + \Delta_1 (e_1, t)$$
$$\dot{e}_2 = -a_1 e_2 + b_3 u_b + \Delta_2 (e, t)$$

where

$$f_1 (e_1) = \frac{1}{\gamma} \left( \frac{1}{2} \left( \frac{\Sigma}{x_{s_1}} \right)^2 - \frac{\Sigma}{x_{s_1}} \right)$$
$$b_1 (e_1) = \frac{1}{\gamma} \left( \frac{1}{2} \left( \frac{\Sigma}{x_{s_1}} \right)^2 - \frac{\Sigma}{x_{s_1}} \right)$$
where $c_2 = x_6 - x_{6\delta}$ is an auxiliary error variable, with $x_6$ considered as a virtual control for (29), with desired value $x_{6\delta}$. The expressions $f_1(e_1)$ and $b_1(e_1)$ are given by $f_1(e_1) = \frac{1}{2} [a_{11} F(s) - f_w(x_T)] - a_{75} x_5 + a_{8g} f(s)$ and $b_1(e_1) = -a_9$. With $e = (e_1, e_2)$, the terms $\Delta_1(e_1, t) = \Delta_3 - \frac{1}{4} s^* \Delta_3$ and $\Delta_2(e, t) = x_{6\delta} - a_{10} x_6$ are the system perturbations. It will be assumed that these perturbations and their first derivatives are bounded as $|\Delta_1(e_1, t)| \leq \Delta_1^+$, $|\Delta_2(e, t)| \leq \Delta_2^+$ and $|\Delta_2(e, t)| \leq \Delta_2^+$.

Selecting

$$x_{6\delta} = -\frac{1}{b_1(e_1)} (f_1(e_1) + \lambda_1 e_0 + \lambda_2 e_1 - u_1)$$

as in [25], where $e_0 = e_1$ and $\dot{u}_1 = -\alpha \psi_{12}(e_1, \dot{e}_1)$, with

$$\psi_{12} = \frac{e_1 + |e_1|^{1/2} \text{sign}(e_1)}{|e_1| + |e_1|^{1/2}}$$

and $\alpha, \lambda_1, \lambda_2 > 0$, and applying the super-twisting control algorithm [12] as

$$u_0 = \frac{1}{b_3} (u_0 + u_2)$$

with $u_0 = -k_{b1} e_2^{1/2} \text{sign}(e_2)$, $\dot{u}_2 = -k_{b2} \text{sign}(e_2)$ and $k_{b1}, k_{b2} > 0$; the system (29)-(32) reduces to

$$\begin{cases}
\dot{e}_0 = e_1 \\
\dot{e}_1 = -\lambda_1 e_0 - \lambda_2 e_1 + u_1 + b_1(e_1) e_2 + \Delta_1 \\
\dot{u}_1 = -\alpha \frac{e_1 + |e_1|^{1/2} \text{sign}(e_1)}{|e_1| + |e_1|^{1/2}} \\
\dot{e}_2 = -a_{10} e_2 - k_{b1} e_2^{1/2} \text{sign}(e_2) + \Delta_2 \\
\dot{u}_2 = -k_{b2} \text{sign}(e_2)
\end{cases}$$

where $\dot{e}_1$ is calculated applying a SM differentiator [19] and the brake valve is considered of the type of valve which can vary its position in a continuous range.

The stability of the closed loop system (33)-(34) is outlined in a step by step procedure. **Step A** Reaching phase of the projection motion (34). **Step B** Stability of the SM dynamics (33) and **Step C** Stability of the zero dynamics $x_T$.

**Step A** Let $q_0 = u_{b2} + \Delta_2(e, t)$, then from the equation (34), it follows that

$$\begin{align*}
\dot{e}_2 &= -a_{10} e_2 - k_{b1} e_2^{1/2} \text{sign}(e_2) + q_0 \\
\dot{q}_b &= -k_{b2} \text{sign}(e_2) + \Delta_2(e, t).
\end{align*}$$

Under the assumption $|\Delta_2(e, t)| \leq \Delta_2^+$, it follows that if $k_{b1} > 0$ and $k_{b2} > 3 \Delta_2^+ + 4 \left( \frac{\Delta_2^+}{k_{b1}} \right)^2$, then $(e_2, q_0) = (0, 0)$ in finite time [23]. Establishing a SM in the manifold $e_2 = 0$ despite of the perturbation $\Delta_2(e, t)$.

**Step B** Taking into account the equation (30) and defining $z_1 = e_1$ and $z_2 = \dot{e}_1$, the motion on the manifold $e_2 = 0$ is given by

$$\begin{align*}
\dot{z}_1 &= z_2 \\
\dot{z}_2 &= -\lambda_1 z_1 - \lambda_2 z_2 - \alpha \frac{z_2 + |z_1|^{1/2} \text{sign}(z_1)}{|z_2| + |z_1|^{1/2}} + \Delta_1(z_1, t)
\end{align*}$$

Under the assumption $|\Delta_1(e_1, t)| \leq \Delta_1^+$, it follows that if $\alpha > \Delta_1^+$, then $(z_1, z_2) = (0, 0)$ in finite time [26], establishing a SM on the manifold $e_1 = 0$ despite of the perturbation $\Delta_1(e_1, t)$.

**Step C** Note that during braking process $x_T > 0$ and with $s = s^*$ due to the control action, the zero dynamics becomes

$$\dot{x}_T = -a_{11} F(s^*) - f_w(x_T) + \Delta_3.$$  \hspace{1cm} (37)

From the vehicle mechanics, the term $f_w(x_T) - \Delta_3$ can be considered to be bounded $|f_w(x_T) - \Delta_3| \leq \Delta_3^+$. In addition, $a_{11} F(s^*) \gg \Delta_3$. Therefore, let $\gamma = a_{11} F(s^*) - \Delta_3^+ \gg \gamma > 0$, and $V = \frac{1}{2} x_T^2$, then $V = -\gamma s_T [a_{11} F(s^*) + f_w(x_T) - \Delta_3^+] < -\gamma x_T$. Hence, $V < -\gamma_0 \sqrt{V}$, where $\gamma_0 = \gamma V_T^2$. Thus, $x_T = 0$ in finite time. Also, from (28) it follows that $x_5 = 0$ in finite time.

**V. SIMULATION RESULTS**

The feasibility of the proposed control scheme are shown in simulations on the wheel model design example, the system parameters are listed in Table 1.

To maximize the friction force, we suppose that slip tracks a constant signal during the simulations $s^* = 0.203$, which produces a value close to the maximum of the function $\phi(s)$. With parameters value presented in Table 1, the $\phi(s)$ function represents the friction relation under a dry surface condition.

![Fig. 3. Control signal for ABS $u_b$.](image1)

![Fig. 4. Longitudinal speed $x_T$ (dashed) and the linear wheel speed $x_5$ (solid).](image2)

The road perturbation is considered as $z_r = 0.1 \cos(10t)$. The control law parameters are, $k_{s1} = 100000$, $k_{s2} = 150000$, $K = \begin{bmatrix} -20 & 173 \end{bmatrix}$, $k_{b1} = 1000$, $k_{b2} = 500$, $\alpha = 100$ and $\lambda_1 = \lambda_2 = 50$. The matrix $A$ is designed such that its eigenvalues are $\{-50, -60, -80 - 70\}$, while $A = 10000$ for HOSM observer design.

The control signal $u_b$ for the ABS is presented in Fig. 3, and the longitudinal speed $v$ and the linear wheel speed $\omega$ are shown in Fig. 4, the ABS controller should be turned off when the longitudinal speed is close to zero.

The Figure 5 shows the slip rate during the braking process. It can be observed the fast convergence to the reference value $s^*$ and Fig. 6 presents the errors $e_1$ and $e_2$. 

![Fig. 5. Longitudinal speed $x_T$ and linear wheel speed $x_5$.](image3)

![Fig. 6. Errors $e_1$ and $e_2$.](image4)
The Figure 7 shows the coordinate $\ddot{x}_{11}$ position during the breaking process. The position is kept constant until the car is almost stopped. On the other hand, Fig. 8 shows the suspension position $\ddot{x}_{2}$, it moves constantly, counteracting the changes on road and wheel.

The control action $u_s$ for the suspension is shown in Fig. 9. The valve can put or extract fluid into the reservoir to obtain the required force. The system arrives to the sliding surface (Fig. 10) and it is maintained there in spite of the unmatched perturbations coming from the road.

VI. CONCLUSIONS

In this work HOSM based controllers for ABS assisted with active suspension have been proposed. In both cases, the simulation results of the closed-loop system are very accurate, taking into account the high uncertainty of the system, namely, parametric variations and neglected dynamics as well as the perturbations from the road.
